Proof that there are no odd perfect numbers

Kouji Takaki

June 05th, 2019

#### 1. Abstract

For y to be a perfect number, if one of the prime factors is p, the exponent of p is an integer  $n(n \ge 1)$ , the prime factors other than p are  $p_1, p_2, p_3, \dots p_r$  and the even exponent of  $p_k$  is  $q_k$ ,

$$y/p^n = (1 + p + p^2 + \dots + p^n) \prod_{k=1}^r (1 + p_k + p_k^2 + \dots + p_k^{q_k}) / (2p^n) = \prod_{k=1}^r p_k^{q_k}$$

must be satisfied. Let m and q be non-negative integers,

$$n = 4m + 1$$
$$p = 4q + 1$$

Letting *b* and *c* be odd integers, satisfying following expressions,

$$b = \prod_{k=1}^{r} p_k^{q_k}$$

$$c = \prod_{k=1}^{r} (1 + p_k + p_k^2 + \dots + p_k^{q_k})/p^n$$

$$2b = c(p^n + \dots + 1)$$

is established. This is a known content. By the consideration of this research paper, since it turns out that if it becomes an odd perfect number when b is a set of prime numbers, it does not become an odd perfect number when b is a set of larger prime numbers including the set and it becomes a solution at infinity, we have obtained the conclusion that there are no odd perfect numbers.

#### 2. Introduction

The perfect number is one in which the sum of the divisors other than itself is the same value as itself, and the smallest perfect number is

$$1 + 2 + 3 = 6$$

It is 6. Whether an odd perfect number exists or not is currently an unsolved problem.

#### 3. Proof

An odd perfect number is y, one of them is an odd prime number p, an exponent of p is an integer n ( $n \ge 1$ ). Let  $p_1, p_2, p_3, \dots p_r$  be the odd prime numbers of factors other than p,  $q_k$  the index of  $p_k$ , and variable a be the sum of product combinations other than prime p.

$$a = \prod_{k=1}^{r} (1 + p_k + p_k^2 + \dots + p_k^{q_k}) \dots \textcircled{1}$$

The number of terms N of variable a is

$$N = \prod_{k=1}^{r} (q_k + 1) \dots 2$$

When y is a perfect number,

$$y = a(1 + p + p^2 + \dots + p^n) - y (n > 0)$$

is established.

$$a \sum_{k=0}^{n} p^{k} / 2 = y$$
$$a \sum_{k=0}^{n} p^{k} / (2p^{n}) = y/p^{n} \dots 3$$

# 3.1. If $q_k$ has at least one odd integer

Letting the number of terms where  $q_k$  is an odd integer be a positive integer u, because  $y/p^n = \prod_{k=1}^r p_k^{q_k}$  is an odd integer, the denominator on the left side of expression ③ has a prime factor 2, from expression ② variable a has more than u prime factor 2 and variable a is an even integer. Therefore  $\sum_{k=0}^n p^k$  must be an odd integer, n is an even integer and u is 1.

# 3.2. When all $q_k$ are even integers

 $y/p^n$  is an odd integer, the denominator on the left side of expression ③ is an even integer, and since N is and odd integer when  $q_k$  are all even integers, variable a is and odd integer. Therefore  $\sum_{k=0}^n p^k$  is necessary to include one prime factor 2,  $\sum_{k=0}^n p^k \equiv 0 \pmod{2}$  is established, and n must be an odd integer.

From 3.1, 3.2, in order to have an odd perfect number, only one exponent of the prime factor of y must be an odd integer and variable a must be an odd integer. We consider the case of 3.2 below.

In order for y to be a perfect number, the following expression must be established.

$$y/p^n = (1+p+p^2+\cdots+p^n) \prod_{k=1}^r (1+p_k+{p_k}^2+\cdots+{p_k}^{q_k})/(2p^n) = \prod_{k=1}^r p_k^{q_k}$$

However,  $q_1, q_2, ..., q_r$  are all even integers.

Here, let b be an integer

$$b = \prod_{k=1}^{r} p_k^{q_k} \dots \textcircled{4}$$

A following expression is established.

$$y/p^n = a(1 + p + p^2 + \dots + p^n)/(2p^n) = b$$

$$a(p^{n+1}-1)/(2(p-1)p^n) = b$$

$$(a-2b)p^{n+1} + 2bp^n - a = 0 \dots 5$$

Because it is an n+1 order equation of p, the solution of the odd prime p is n+1 at most.

$$(ap - 2bp + 2b)p^n = a$$

Since ap - 2bp + 2b is an odd integer,  $a/p^n$  is an odd integer, which is c.

$$ap - 2bp + 2b = c (c > 0) \dots$$

$$(2b - a)p = 2b - c$$

Since variable a is an odd integer, 2b-a is an odd integer and  $2b-a \neq 0$  p = (2b-c)/(2b-a)

Since  $n \ge 1$ 

$$a - c = cp^n - c \ge cp - c > 0$$

a > c

is.

From equation 6

$$2b(p-1) - (ap - c) = 0$$

$$2b - c(p^{n+1} - 1)/(p - 1) = 0$$

 $(p^n + \cdots + 1)/2$  is an odd integer, n = 4m + 1 is required with m as an integer.

$$2b(p-1) = c(p^{n+1} - 1)$$

$$2b = c(p^n + \dots + 1)$$

$$2b = c(p+1)(p^{n-1} + p^{n-3} + \dots + 1) \dots$$

b is an odd integer when p + 1 is not a multiple of 4. It is necessary that p - 1 be a multiple of 4. A positive integer is taken as q.

$$p = 4q + 1$$

is established.

When p > 1

$$p^n - 1 < p^n$$

$$(p^n - 1)/(p - 1) < p^n/(p - 1)$$

$$p^{n-1} + \dots + 1 < p^n/(p-1) \dots \otimes$$

Since p is an odd prime number satisfying p = 4q + 1 and  $p \ge 5$ 

$$p^{n-1} + \dots + 1 < p^n/4$$

$$2b - a = c(p^n + \dots + 1) - cp^n = c(p^{n-1} + \dots + 1)$$

$$2b - a < cp^{n}/4 = a/4$$

Let  $a_k$  and  $b_k$  be integers and if

$$a_k = 1 + p_k + p_k^2 + \dots + p_k^{q_k}, \ b_k = p_k^{q_k},$$

$$a_k - b_k < b_k/(p_k - 1)$$

$$a_k < b_k p_k / (p_k - 1)$$

$$a = \prod_{k=1}^{r} a_k < \prod_{k=1}^{r} b_k p_k / (p_k - 1) = b \prod_{k=1}^{r} p_k / (p_k - 1)$$
$$a/b < \prod_{k=1}^{r} p_k / (p_k - 1)$$

When r = 1, since a/b < 3/2 is established, it becomes inappropriate contrary to inequality @.

From expression ⑦,

$$b = c(p+1)/2 \times (p^{n-1} + p^{n-3} + \dots + 1)$$

holds. Since (p+1)/2 is the product of only prime numbers of b, let  $d_k$  be the index,

$$(p+1)/2 = \prod_{k=1}^{r} p_k^{d_k}$$

$$p = 2 \prod\nolimits_{k=1}^{r} p_k^{\ d_k} - 1$$

From  $a = cp^n$  and expression  $\bigcirc$ ,

$$2bp^n = a(p^n + \dots + 1)$$

$$a(p^{n} + \dots + 1)/(2bp^{n}) = 1 \dots (A)$$

When r = 1,

$$a = (p_1^{q_1+1} - 1)/(p_1 - 1)$$

$$b = p_1^{q_1}$$

Equation (A) does not hold since there is no odd perfect number when r = 1.

Let R be a rational number,

$$R = a(p^n + \dots + 1)/(2bp^n)$$

Let b' be a rational number and let A and B to be an integer,

$$b' = (p_k^{q_k+1} - 1)/(p_k^{q_k}(p_k - 1)) > 1$$

$$A = (p_k^{q_k+1} - 1)/(p_k - 1)$$

$$B = p_k^{q_k}$$

Multiplying R by b', there are both cases that  $p_k$  increases p or does not change. When multiplied by b', the rate of change of R is  $Ap^n(p'^n + \dots + 1)/(Bp'^n(p^n + \dots + 1))$ , if p after variation is p'. If the rate of change of R is 1,

$$Ap^{n}({p'}^{n} + \dots + 1)/(Bp'^{n}(p^{n} + \dots + 1)) = 1$$

$$Ap^{n}(p'^{n} + \dots + 1) = Bp'^{n}(p^{n} + \dots + 1)$$

This expression does not hold, since the right side is not a multiple of p when p' > p, and A > B holds when p' = p. Due to this operation, R may be larger or smaller than the original value, since the rate of change of R does not become 1.

From  $R \neq 1$  and  $a = cp^n$  for some r, also multiplying fractions  $b' = A_{r+1}/B_{r+1}$ ,  $b'' = A_{r+2}/B_{r+2}$ ,  $\cdots b'' \cdots' = A_x/B_x$ , if R = 1 holds finally,

$$a(p^{n} + \dots + 1)/(2bp^{n}) \times A_{r+1}p^{n}(p_{r+1}^{n} + \dots + 1)/(B_{r+1}p_{r+1}^{n}(p^{n} + \dots + 1))$$

$$\times A_{r+2}p_{r+1}^{n}(p_{r+2}^{n} + \dots + 1)/(B_{r+2}p_{r+2}^{n}(p_{r+1}^{n} + \dots + 1)) \dots A_{x}p_{x-1}^{n}(p_{x}^{n} + \dots + 1)/(B_{x}p_{x}^{n}(p_{x-1}^{n} + \dots + 1)) = 1$$

$$a/(2b) \times A_{r+1}/B_{r+1} \times A_{r+2}/B_{r+2} \dots A_x({p_x}^n + \dots + 1)/(B_x {p_x}^n) = 1$$

$$a(p_x^n + \dots + 1)A_{r+1}A_{r+2} \dots A_x = 2bp_x^n B_{r+1}B_{r+2} \dots B_x$$

$$cp^{n}(p_{x}^{\ n}+\cdots+1)A_{r+1}A_{r+2}...A_{x}=2bp_{x}^{\ n}B_{r+1}B_{r+2}...B_{x}$$

When  $p_x > p$ , it becomes inconsistent since the right side of this expression does not include p as a factor.

When  $p_x = p$ ,

$$cp^n(p^n+\cdots+1)A_{r+1}A_{r+2}\dots A_x=c(p^n+\cdots+1)p^n$$

$$A_{r+1}A_{r+2}...A_x = 1$$

It becomes contradiction, since this expression is not established. Therefore,  $a=cp^n$  holds at one point where R=1.

Assuming that R = 1 in some r by multiplying fractions  $b' = A_{r+1}/B_{r+1}$ ,  $b'' = A_{r+2}/B_{r+2}$ ,  $\cdots b'' \cdots' = A_x/B_x$ , if R = 1 holds,

$$\begin{split} 1 \times A_{r+1} p^n (p_{r+1}{}^n + \dots + 1) / (B_{r+1} p_{r+1}{}^n (p^n + \dots + 1)) \times A_{r+2} p_{r+1}{}^n (p_{r+2}{}^n + \dots \\ &+ 1) / (B_{r+2} p_{r+2}{}^n (p_{r+1}{}^n + \dots + 1)) \dots A_x p_{x-1}{}^n (p_x{}^n + \dots + 1) / (B_x p_x{}^n (p_{x-1}{}^n + \dots + 1)) \\ &+ \dots + 1)) = 1 \end{split}$$

$$A_{r+1}A_{r+2}...A_xp^n(p_x^n+\cdots+1) = B_{r+1}B_{r+2}...B_xp_x^n(p^n+\cdots+1)$$

When  $p_x > p$ , it becomes inconsistent since the right side of this expression does not include p as a factor.

When  $p_x = p$ ,

$$A_{r+1}A_{r+2} ... A_x = B_{r+1}B_{r+2} ... B_x$$

is established. It becomes contradiction. Therefore, if b is a set of primes and R=1 when n is fixed, it does not become an odd perfect number when b is a larger set including the set.

Assuming that R=1 in some r by multiplying fractions  $b'=A_{r+1}/B_{r+1}$ ,  $b''=A_{r+2}/B_{r+2}$ ,  $\cdots b''\cdots'=A_x/B_x$ , if R=1 holds. At this time, assuming that n also changes, the change rate when multiplying by  $A_{r+1}/B_{r+1}$  is

$$A_{r+1}p^{n}(p_{r+1}^{n_{r+1}}+\cdots+1)/(B_{r+1}p_{r+1}^{n_{r+1}}(p^{n}+\cdots+1))$$

$$\begin{split} 1\times A_{r+1}p^{n}(p_{r+1}{}^{n_{r+1}}+\cdots+1)/(B_{r+1}p_{r+1}{}^{n_{r+1}}(p^{n}+\cdots+1))\times A_{r+2}p_{r+1}{}^{n_{r+1}}(p_{r+2}{}^{n_{r+2}}+\cdots\\ &+1)/(B_{r+2}p_{r+2}{}^{n_{r+2}}(p_{r+1}{}^{n_{r+1}}+\cdots+1)) ... A_{x}p_{x-1}{}^{n_{x-1}}(p_{x}{}^{n_{x}}+\cdots\\ &+1)/(B_{x}p_{x}{}^{n_{x}}(p_{x-1}{}^{n_{x-1}}+\cdots+1)) = 1 \end{split}$$

$$A_{r+1}A_{r+2} \dots A_x p^n (p_x^{n_x} + \dots + 1) = B_{r+1}B_{r+2} \dots B_x p_x^{n_x} (p^n + \dots + 1)$$

When  $n = n_x$  it becomes contradiction like above proof.

When  $n_x < n$ , a contradiction arises in the case of  $p_x \ne p$  since prime number p is not included in the right side. It becomes inconsistent in the case of  $p_x = p$  since only the left side includes the prime number p. A contradiction arises similarly when  $n_x > n$ . Therefore, when n takes an arbitrary value and b is a prime set with R = 1, it does not become an odd perfect number when b is a larger set including the set.

Equation (A) holds when  $(a, b, p, n) = (\infty, \infty, p, n)$ . Since b is infinite and all set of prime numbers are included in b as a subset, equation (A) is not established in the range of  $a < \infty$  and  $b < \infty$ . Therefore, there are no odd perfect numbers.

### 4. Complement

$$\begin{split} 2bp^{n}(p-1) &= a(p^{n+1}-1) \\ 2 &= a(p^{n+1}-1)/(bp^{n}(p-1)) \\ 2 &= (p_{1}^{q_{1}+1}-1)(p_{2}^{q_{2}+1}-1)...(p_{r}^{q_{r}+1}-1)(p^{n+1}-1) \\ & / (p_{1}^{q_{1}}p_{2}^{q_{2}}...p_{r}^{q_{r}}p^{n}(p_{1}-1)(p_{2}-1)...(p_{r}-1)(p-1)) \\ 2(p_{1}^{q_{1}+1}-p_{1}^{q_{1}})(p_{2}^{q_{2}+1}-p_{2}^{q_{2}})...(p_{r}^{q_{r}+1}-p_{r}^{q_{r}})(p^{n+1}-p^{n}) \\ &= (p_{1}^{q_{1}+1}-1)(p_{2}^{q_{2}+1}-1)...(p_{r}^{q_{r}+1}-1)(p^{n+1}-1) \end{split}$$

We consider when r = 2.

$$({p_1}^{q_1+1}-1)({p_2}^{q_2+1}-1)(p^{n+1}-1)=2({p_1}^{q_1+1}-{p_1}^{q_1})({p_2}^{q_2+1}-{p_2}^{q_2})(p^{n+1}-p^n)$$

Let s, t, u be integers,

$$s = p_1^{q_1+1} - 1$$

$$t = p_2^{q_2 + 1} - 1$$

$$u = p^{n+1} - 1$$

are

$$stu = 2(p_1^{q_1+1} - 1 - (p_1^{q_1} - 1))(p_2^{q_2+1} - 1 - (p_2^{q_2} - 1))(p^{n+1} - 1 - (p^n - 1))$$

$$stu = 2(s - (s + 1)/p_1 + 1)(t - (t + 1)/p_2 + 1)(u - (u + 1)/p + 1)$$

$$pp_1p_2stu = 2((s+1)p_1 - (s+1))((t+1)p_2 + (t+1))((u+1)p + (u+1))$$

$$pp_1p_2stu = 2(s+1)(p_1-1)(t+1)(p_2-1)(u+1)(p-1)$$

$$stu/((s+1)(t+1)(u+1)) = 2(p_1-1)(p_2-1)(p-1)/(p_1p_2p)$$

Since stu/((s+1)(t+1)(u+1)) is a monotonically increasing function for variables s, t and u, if

$$s \ge 3^{2+1} - 1 = 26$$
,  $p_1 = 3$ ,  $q_1 = 2$ 

$$t \ge 7^{2+1} - 1 = 342, p_2 = 7, q_2 = 2$$

$$u \ge 5^2 - 1 = 24$$
,  $p = 5$ ,  $n = 1$ 

holds,

$$stu/((s+1)(t+1)(u+1)) \ge 26 \times 342 \times 24/(27 \times 343 \times 25) = 7904/8575$$

$$2(p_1 - 1)(p_2 - 1)(p - 1)/(p_1p_2p) = 2 \times 2 \times 6 \times 4/(3 \times 7 \times 5) = 32/35$$

Since stu/((s+1)(t+1)(u+1)) is limited to 1 when s, t and u are infinite, stu/((s+1)(t+1)(u+1)) < 1

If  $f(p_1, p_2, p) = 2(p_1 - 1)(p_2 - 1)(p - 1)/(p_1p_2p)$  holds, it is sufficient to consider a combination where  $f(p_1, p_2, p) < 1$ .

$$f(3,7,5) = 2 \times 2 \times 6 \times 4/(3 \times 7 \times 5) = 32/35$$

$$f(3,11,5) = 2 \times 2 \times 10 \times 4/(3 \times 11 \times 5) = 32/33$$

$$f(3,13,5) = 2 \times 2 \times 12 \times 4/(3 \times 13 \times 5) = 64/65$$

$$f(3,17,5) = 2 \times 2 \times 16 \times 4/(3 \times 17 \times 5) = 256/255$$

$$f(3,7,13) = 2 \times 2 \times 6 \times 12/(3 \times 7 \times 13) = 96/91$$

$$f(3,5,17) = 2 \times 2 \times 4 \times 16/(3 \times 5 \times 17) = 256/255$$

From the above, when r = 2, a combination  $(p_1, p_2, p) = (3,7,5), (3,11,5), (3,13,5)$  can be considered.

Let 
$$q_k$$
 be 2 and  $n = 1$ , if  $g(p_1, p_2, p) = (p_1^3 - 1)(p_2^3 - 1)(p^2 - 1)/(p_1^3 p_2^3 p^2)$ ,  $g(3,7,5) = 26 \times 342 \times 24/(3^3 7^3 5^2) = 7904/8575 > 32/35$   $g(3,11,5) = 26 \times 1330 \times 24/(3^3 11^3 5^2) = 55328/59895$   $g(3,13,5) = 26 \times 2196 \times 24/(3^3 13^3 5^2) = 3904/4225$ 

Since the function g is the minimum in the case of  $q_k = 2$  and n = 1, there is no solution  $q_k$  and n when g > f, so the case of  $(p_1, p_2, p) = (3,7,5)$  becomes unsuitable.

$$\begin{split} \text{stu}/((s+1)(t+1)(u+1)) &= 2(p_1-1)(p_2-1)(p-1)/(p_1p_2p) \\ (p_1^{q_1+1}-1)(p_2^{q_2+1}-1)(p^{n+1}-1)/(p_1^{q_1+1}p_2^{q_2+1}p^{n+1}) \\ &= 2(p_1-1)(p_2-1)(p-1)/(p_1p_2p) \end{split}$$

If 
$$F(p_1, p_2, p) = (p_1 - 1)(p_2 - 1)(p - 1)/(p_1p_2p)$$
,  
 $F(p_1^{q_1+1}, p_2^{q_2+1}, p^{n+1}) = 2F(p_1, p_2, p)$
