The concept of time

Abstract

In physics, the begin of the universe poses interpretation problems. This can be resolved by restricting the range of proper time to a subset of the range of events.

1 Physical reality

Physical reality appears to exist for about 13.8 billion years. Thus, after that starting instant the proper time clock ticks. Before that instant the creation of physical reality must have taken some action but that phase is not covered by the proper time range that observers can perceive. Any model of physical reality must incorporate this preparation phase and must deliver a proper explanation why the observable proper time range starts after the preparation phase finished. With other words the model of physical reality must belong to the category of the self-creating models.

2 Modeling physical reality

The preparation phase must generate a base model in which physical reality can evolve from a founding structure to a full-blown dynamic model that can be observed as the dynamic field that represents the universe, which exists in physical reality. That universe must be filled with all the discrete objects that can be observed in this field.

3 The Hilbert Book Model

The Hilbert Book Model is a self-creating model that owns a simple foundation from which a base model emerges that offers a huge structured read-only repository that archives all dynamic geometric data of all elementary particles that are embedded in a dynamic field. It uses quaternions as storage bins that contain a scalar time-stamp and a three-dimensional location. After sequencing the time-stamps, the archive tells the life stories of the elementary particles. The range of proper time values corresponds to the range of the archived time-stamps. Thus, this arrangement fits the requirements for the self-creating model.

In the preparation phase, for each elementary particle, a private stochastic process generates the hop landing locations of an ongoing hopping path that recurrently regenerates a coherent hop landing location swarm. The characteristic function of this process ensures that the same location density distribution describes this hop landing location swarm. After sequencing the time-stamps, the archived hopping path tells the life story of the elementary particle in the realm of its floating platform. That platform is implemented by a private quaternionic separable Hilbert space.

This life story corresponds with the ongoing embedding of the hop landing locations into the dynamic field that we call our universe, and that is implemented by a continuum eigenspace of a normal

operator that resides in a background non-separable Hilbert space. All elementary particles embed their hop landings in this dynamic field.

The elementary particles act as elementary modules. Together they constitute all modules and modular systems that exist in our universe. Thus this dynamic field reflects the activity of all elementary particles. Each module can act as an observer. All observers must travel with a scanning proper time window. They can only receive information via the embedding field, and for them, that information was archived with a historical timestamp.

Thus, the model covers a larger number of activities than the observable range of proper time covers.

3.1 Two views

This is why the Hilbert Book Model supports a creator's view as well as an observer's view. The creator's view covers all activities. The perception of the modules is restricted to the observer's view.
